

静态时序分析与逻辑综合 STA & SYN

韩炳晋 2025/06/15

Sec. 1 静态时序分析(Static Timing Analysis, STA)

STA是一种在数字IC设计中用于验证电路时序正确性的重要方法。

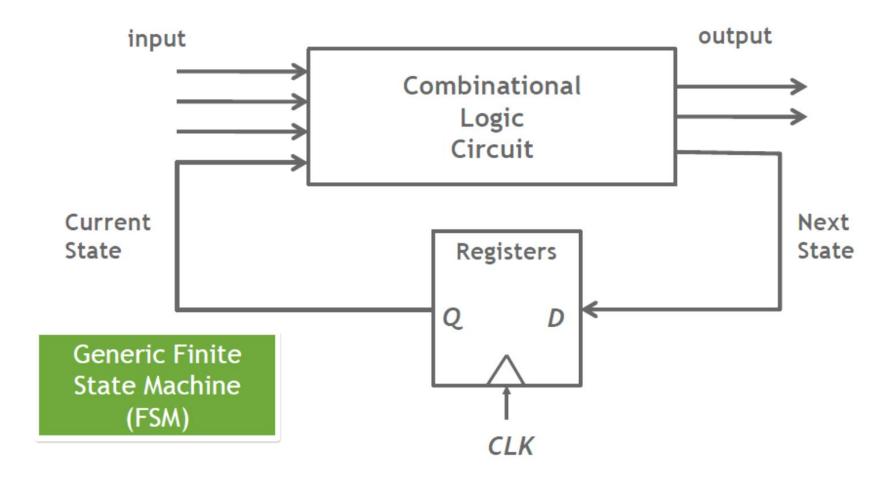

在YSYX的yosys-sta中,利用iSTA工具,你会得到这样的报告:

• •

30813_:D (DFF_X1)	ļ	0.001	0.000	0.006	ļ	0.000	1.373f
 clock (port) clock (clock pot)	 2044	 1.941	0.000	 0.000	 NA	 0.000	0.000r
clock (clock net) _30813_:CK (DFF_X1)	2044	0.001	0.000	0.000	IVA 	0.000	0.000r

į į		 		 	 		0.000(0.0000) 1.084
data require time data arrival time	 -	 				 	1.373
slack (VIOLATED)	 +	 +	 +	 +	 +	 +	-0.289

它的原理是什么,如何实现的?

静态时序分析-时序逻辑

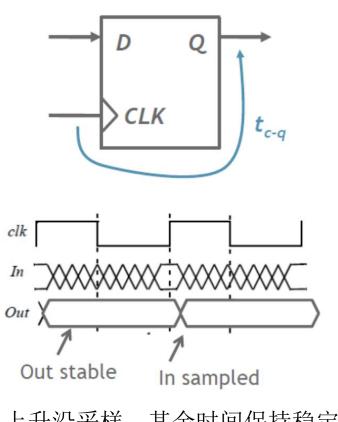

时序逻辑 = 组合逻辑 + 寄存器(触发器)

目前不考虑带锁存器的时序逻辑

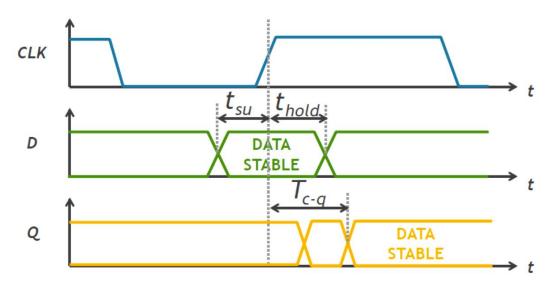

图片来源于:华南理工大学郑彦祺老师《数字集成电路》课件。

静态时序分析-触发器的Setup/Hold Time以及传输延迟

上升沿采样,其余时间保持稳定

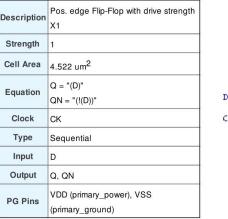

术语	解释
建立(Setup)时间	时钟沿到达之前,数据信号(D)必须保持 有效的时间。
保持(Hold)时间	时钟沿到达之后,数据信号(D)必须继续保持有效的时间。
传输延迟	D输入经过时钟沿后,传播到Q输出所需的时间。

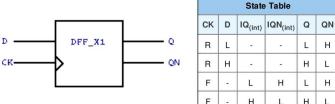

静态时序分析-标准单元库中的Setup/Hold以及传输延迟

(以Nangate45为例)

RTFM:

Propagation Delay [ns]							
Input Transition [ns]		0.00	009	0.1462			
Load Capacitance [fF]		0.3656	60.73	0.3656	60.73		
CK to Q	fall	0.05	0.11	0.06	0.12		
	rise	0.05	0.13	0.06	0.14		
CK to QN	fall	0.03	0.10	0.04	0.11		
	rise	0.04	0.12	0.05	0.13		

Constraints Time [ns]				
Setup CK to D	fall	0.06		
Setup CK to D	rise	0.04		
Hold CK to D	fall	0.12		
Hold CK to D	rise	0.10

静态时序分析-标准单元库中的Setup/Hold以及传输延迟

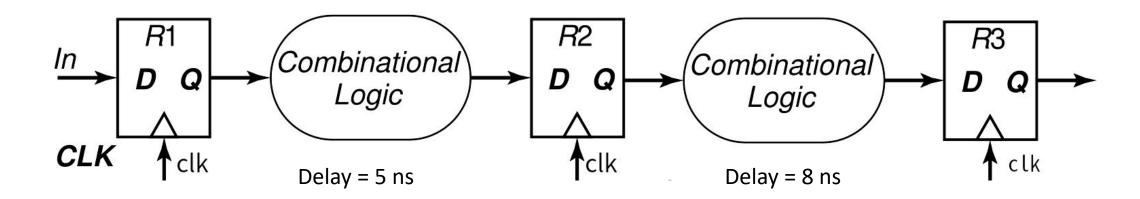

(以Nangate45为例)

RTFSC: Liberty File: NangateOpenCellLibrary_typical.lib

```
cell (DFF_X1) {
         pin (D) { // setup and hold time
                   timing () {
                              related pin
                                                      : "CK";
                             timing type
                                                     : hold rising;
                             fall constraint(Hold 3 3) {
                                        index 1 ("0.00117378,0.0449324,0.198535"); //input net transition
                                        index 2 ("0.00117378,0.0449324,0.198535"); //total output net capacitance
                                        values ("0.001650,0.010970,0.010626", \
                                                "0.004131, 0.010748, 0.006379", \
                                                "0.143222,0.153005,0.144764");
                             rise constraint(Hold 3 3) {
         pin (Q) { // propagation delay
                             timing () {
         . . .
                                        cell fall(Timing 7 7) {
         . . .
                                        cell rise(Timing 7 7) {
```

Liberty文件格式可参考: Alan Mishchenko. Liberty Reference Manual. 2007. https://people.eecs.berkeley.edu/~alanmi/publications/other/liberty07_03.pdf

静态时序分析-关键路径(Critical Path)

不考虑Setup和寄存器传输延迟:

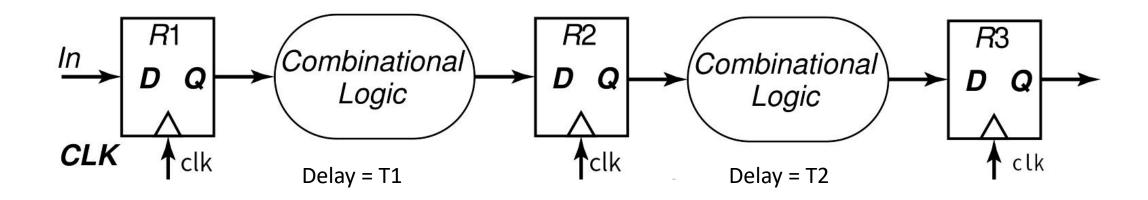

最大的Tclk = 8ns,最高频率为125MHz Delay = 8ns的这条路径被称为关键路径

考虑Setup和寄存器传输延迟:

最大的Tclk=8ns + Tsu + Tcq,最高频率变低

Require Time = Tclk - Tsu Arrival Time = Tlogic + Tcq

静态时序分析-Hold Constraint

Hold Time: 时钟沿到达之后,数据信号(D)必须继续保持有效的时间。 也就是说,Hold Time限制了组合逻辑的最小延迟。

Tlogic > Thold - Tcq

静态时序分析-读时序分析报告

Require Time = Tclk - Tsu Arrival Time = Tlogic + Tcq

Point	Fanout	Capacitance	Resistance	Transition	Delta Delay	Incr	Path

Sec. 2 逻辑综合

逻辑综合是指将电路的行为描述(如RTL级Verilog代码)转换为可实现的门级电路网表的过程。 一生一芯中使用Yosys+ABC完成了综合。

assign c = a & b;
assign y =
$$\sim$$
c;
AND2_X1 _001_(.Y(c), .A(a), .B(b));
INV_X1 _002_(.Y(y), .A(c), .B(b));

逻辑综合-预备知识-AIG

AIG 是仅由二输入与门及隐式反相边构成的有向无环图 (DAG)

例如,一个异或运算 $(z = x \oplus y)$ 可以用如下的 **AIG** (图 2-4) 表示。其中,方形节点表示输入和输出,圆形节点表示与门,虚线箭头表示信号取反。由于 **AIG** 的结构简单,广泛应用于逻辑综合中。

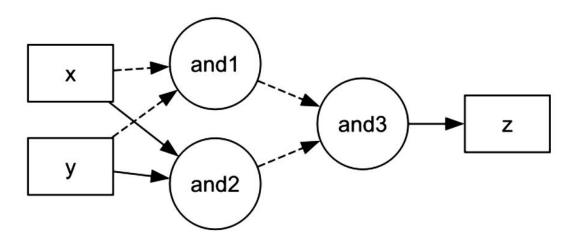

图 2-4 表示异或运算的与非图

逻辑综合-预备知识-Structural hashing (strashing)

结构哈希是一种消除结构冗余、提高图结构规范性的优化方法。

它的基本思想是: 当向AIG中添加一个新的AND门节点时,如果该节点与现有节点在逻辑结构上是等价的(即有相同的输入,输入顺序可以交换),那么就复用现有节点,而不是新建一个功能完全一样的新节点。

不同的策略:

- One-level strashing
- Two-level strashing

```
Aig_Node * OperationAnd( Aig_Man * p, Aig_Node * n1, Aig_Nodee * n2 )
  Aig_Node * res, * cand, * temp; Aig_NodeArray * class;
   /*** trivial cases ***/
  if (n1 == n2)
                                                     return n1;
  if (n1 == NOT(n2))
                                                     return 0;
  if (n1 == const)
                                                     return 0 or n2;
  if (n2 == const)
                                                     return 0 or n1;
  if (n1 < n2) { /*** swap the arguments ***/
      temp = n1; n1 = n2; n2 = temp;
  /*** one level structural hashing ***/
  res = HashTableLookup(p->pTableStructure, n1, n2);
  if (res)
                                                     return res:
   res = CreateNode(p, n1, n2);
   HashTableAdd( p->pTableStructure, res );
                                                     return res;
                 一阶结构哈希的伪代码
```

伪代码来源于: Mishchenko, A., Chatterjee, S., Jiang, R., Brayton, R., n.d. FRAIGs: A Unifying Representation for Logic Synthesis and Verification.

逻辑综合-Rewrite

Rewrite 是一种基于贪心算法的逻辑优化方法,可用于优化电路的面积和时序。

核心思想:

在电路网络中,识别小规模的局部子图,查找等价但结构更优的替换模式,用以降低门数或减少电路深度。

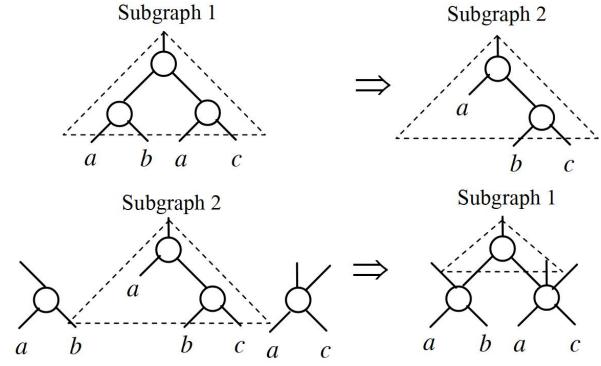

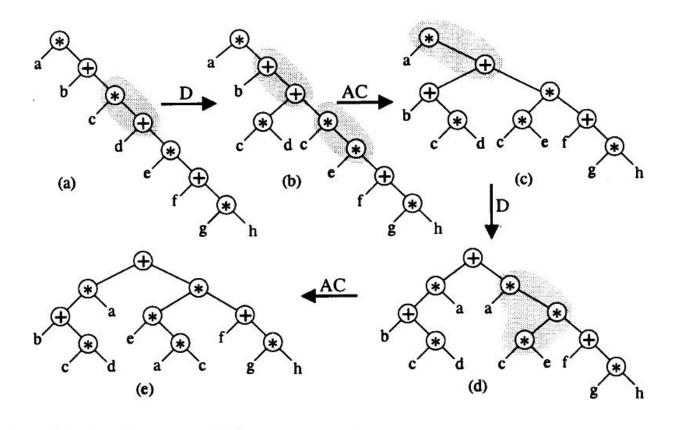

Figure 3. Two cases of AIG rewriting of a node.

逻辑综合-Balance

Balance是在逻辑综合中通过应用结合律、交换律和分配律等代数变换,重新组织布尔表达式的树结构,以减少电路的逻辑层数。

ACD rules:

A: Associative

C: Cmmutative

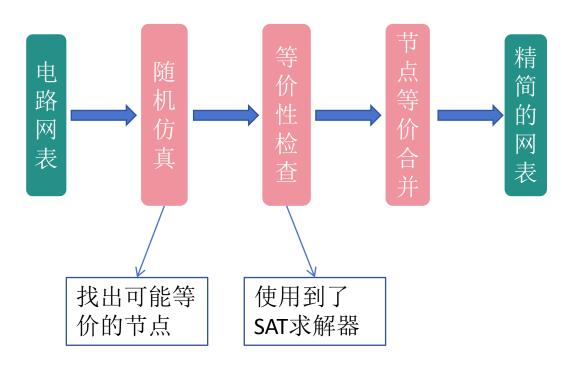

D: Distributive

Fig. 9. Application of ACD rules to optimize performance.

Cortadella, J., 2003. Timing-driven logic bi-decomposition. IEEE Trans. Comput.-Aided Des. Integr. Circuits Syst. 22, 675–685.

逻辑综合-SAT-Sweeping

SAT-Sweeping旨在通过SAT(可满足性)判定方法,识别并合并电路中的功能等价节 点,减少电路规模。

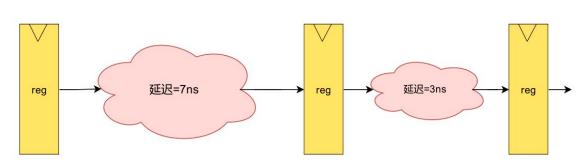

最早提出: Kuehlmann, A., 2004. Dynamic transition relation simplification for bounded property checking, in: IEEE/ACM International Conference on Computer Aided Design, 2004. ICCAD-2004.

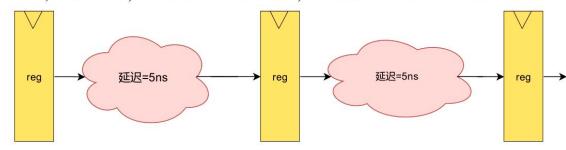

Mishchenko, A., Chatterjee, S., Jiang, R., Brayton, R., n.d. FRAIGs: A Unifying Representation for Logic Synthesis and Verification. 15

逻辑综合-Retiming

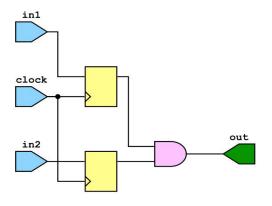

重定时是一项在保持电路功能等价的前提下,通过移动寄存器来改善电路性能的优化技术。其目标通常分为两类:最小化延迟与最小化面积

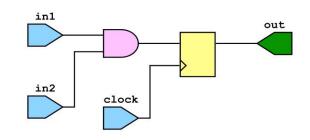

a) 重定时前, 关键路径延时为 7ns, 理想条件下最高频率为 143Mhz

b) 重定时后, 关键路径延时为 5ns, 理想条件下最高频率为 200Mhz 最小化延时

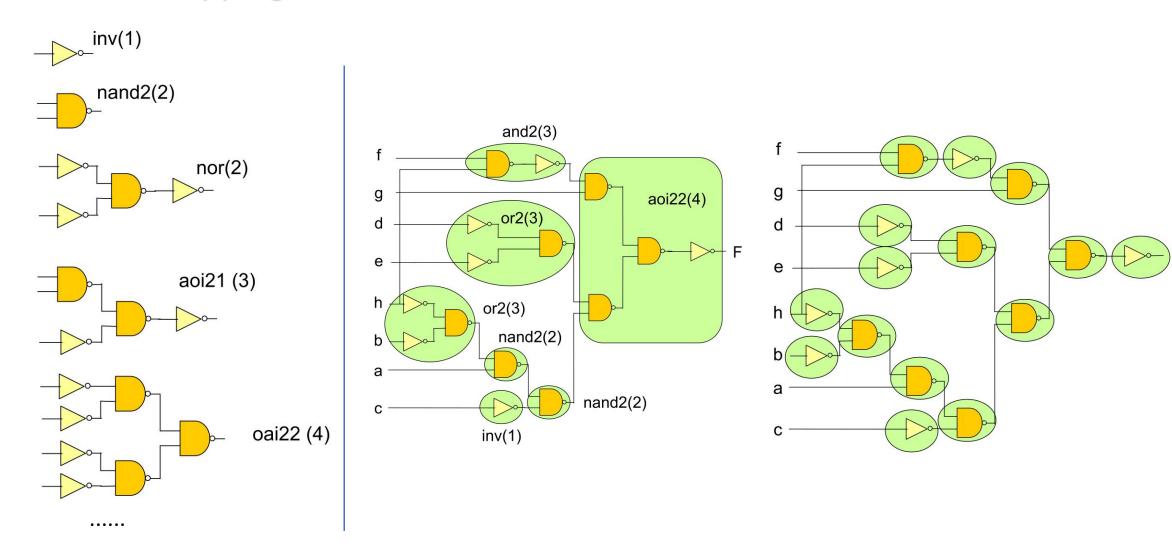

a) 重定时前, 电路有 2 个寄存器和 1 个与门

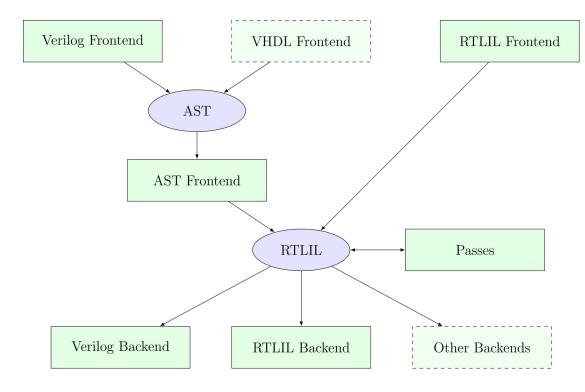

b) 重定时后,电路有1个寄存器和1个与门 最小化面积

逻辑综合-Mapping

逻辑综合-Yosys综合流程

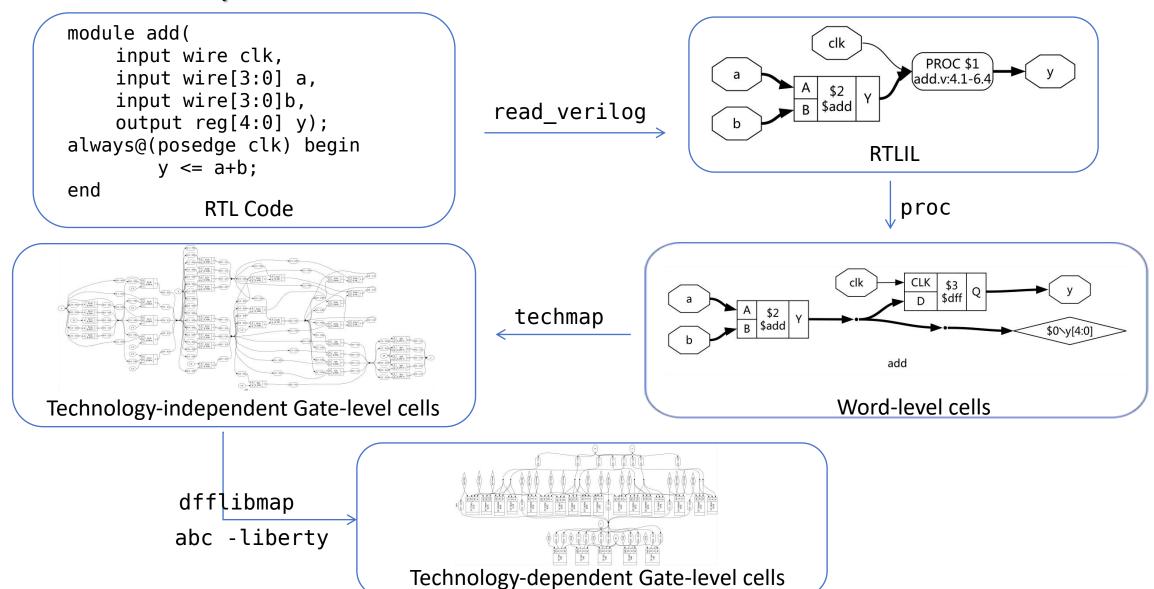

Yosys simplified data flow

General data- and control-flow of a synthesis tool

图片来源于: https://yosyshq.readthedocs.io

逻辑综合-Yosys综合流程示例

逻辑综合-Yosys调用ABC进行综合优化

```
module alu(
   input [7:0] A,
                         // 输入操作数A
   input [7:0] B,
                      // 输入操作数B
   input [2:0] opcode, // 操作码
                         // 结果
   output reg [7:0] Y,
   output reg carry
);
always @(*) begin
    case(opcode)
       3'b000: \{carry, Y\} = A + B; // 加法
       3'b001: \{carry, Y\} = A - B;
                                   // 减法
       3'b010: Y = A \& B;
                                    // 按位与
       3'b011: Y = A \mid B;
                                    // 按位或
       3'b100: Y = A ^ B;
                                    // 按位异或
       3'b101: Y = \sim A;
                                    // A取反
       default: Y = 8'b0;
    endcase
end
endmodule
```

Baseline:

```
read_verilog alu.v
synth
abc -liberty merged.lib -script "+map;stime;"
```

结果:

```
Area = 168.91 Delay = 283.67 ps
```

Yosys 0.44 (git sha1 80ba43d26)

逻辑综合-Yosys调用ABC进行综合优化-面积/延迟

Baseline: Area = 168.91 Delay = 283.67 ps

面积优化:

```
read_verilog alu.v
synth -top alu
abc -liberty merged.lib -script "+strash; fraig; balance -l; rewrite -l; refactor -l;
balance -l; rewrite -l; rewrite -zl; balance -l; refactor -zl; rewrite -zl; balance
-l;map;stime;"

Area = 148.43 Delay = 316.03 ps
```

面积减小12.12%, 延迟增加11.41%

延迟优化:

```
read_verilog alu.v
synth -top alu
abc -liberty merged.lib -script "+strash; balance; rewrite; refactor; balance;
rewrite; rewrite -z; balance; refactor -z; rewrite -z; balance; map; upsize; stime"

Area = 228.23 Delay = 208.86 ps
```

面积增加35.12%, 延迟减小26.37%

逻辑综合-Yosys调用ABC进行Retiming

```
module mac(
        input clk,
        input [7:0]A,
        input [7:0]B,
        input [15:0]C,
        output reg[16:0]Y
);
reg [15:0] multi_result;
always@(posedge clk) begin
        multi result <= A*B;</pre>
        Y = multi result + C;
end
endmodule
```

Baseline:

```
read_verilog mac.v

synth -top mac

abc -clk clk -liberty merged.lib -script "+strash;map;stime;"

Area = 650.37 Delay = 612.45 ps
```

使用retiming:

```
read_verilog mac.v

synth -top mac

abc -clk clk -liberty merged.lib -script "+strash; retime -M 4;

map;stime;"

Area = 651.17 Delay = 337.03 ps
```

面积增加0.12%, 延迟减小44.97%
